Lead71 Vercel Function Issue Resolution

Incident summary | 31 October 2026

What changed

I updated the Lead71 card scan workflow so Gemini is the primary classifier and the existing manual parser is used if AI classification cannot complete. I also added the approved second-layer fields. The changes worked in my local environment.

What went wrong

After I pushed the code to GitHub, the hosted Vercel function returned a 500 FUNCTION_INVOCATION_FAILED error. That meant Vercel could not complete the server-side request, even though the local app was working. The Vercel project that hosts staging is under Haroon Bhai's account. A GitHub push did not by itself complete the required Vercel redeploy, and I could not finish that redeploy from my account.

This was a Vercel function/deployment issue. The browser showed the 500 because the hosted function was not running the updated code successfully. The error was not proof that the Gemini classifier itself had failed.

How it was resolved

Haroon Bhai checked the staging project in his Vercel account, fixed the Vercel function deployment issue, and redeployed the updated code. Redeploying made Vercel build and serve the current GitHub version instead of relying on the locally tested copy. After that redeploy, the staging function worked again.

In simple terms: the code was ready in GitHub and worked locally, but the hosted staging function needed an owner with access to the Vercel project to correct and redeploy it. Haroon Bhai completed that Vercel-side step.

Production status

The changes were not deployed to Lead71 production as part of this fix. The Gemini classification and approved second-layer fields were addressed in staging; production remains separate from this staging redeploy.
